GRIEF MANAGEMENT IN CHILDREN

The death of a cherished pet creates a sense of loss for adults and produces a predictable chain of emotions. The stages of grief are typically denial, sadness, depression, guilt, anger, and finally, relief or recovery. However, the effects on children vary widely depending upon the child's age and maturity level. *The basis for their reaction is their ability to understand mortality and death.*

Two and Three Year Olds

Children who are two or three years old typically have no understanding of death. They often consider it a form of sleep. They can be told that their pet has died and will not return. Common reactions to this include temporary loss of speech and generalized distress. The two or three year old should be reassured that the pet's failure to return is unrelated to anything the child may have said or done. Typically, a child in this age range will readily accept another pet in place of the deceased one.

Four, Five, and Six Year Olds

Children in this age range have some understanding of death but in a way that relates to a continued existence. The pet may be considered to be living in the sky, underground or in heaven while continuing to eat, breathe, and play. Alternatively, the child may believe that the pet is asleep at another location. A return to life or to the home may be expected if the child views death as temporary.

Children at this age often feel that any anger they had for the pet may be responsible for its death. This view should be refuted because they may also translate this belief to the death of family members in the past. Some children also see death as contagious and begin to fear that their own death or that of others they care for is imminent. They should be reassured that death is not contagious and that their pet's death is in no way connected to their health or when they are going to die.

Manifestations of grief in this age group often take the form of disturbances in bladder and bowel control, eating, and sleeping. This is best managed by parent-child discussions that allow the child to express feelings and concerns. Several brief discussions are generally more productive than one or two prolonged sessions.

Seven, Eight, and Nine Year Olds

The irreversibility of death becomes real to these children. They usually do not personalize death, thinking it cannot happen to them. However, some children may develop concerns about death of their parents. They may become very curious about death and its implications. Parents should be ready to respond frankly and honestly to questions that may arise.

Several manifestations of grief may occur in these children, including the development of school problems, learning problems, antisocial behavior, hypochondriacal concerns, or aggression. Additionally, withdrawal, over-attentiveness, or clinging behavior may be seen. Based on grief reactions to loss of parents or siblings, it is likely that these symptoms may not occur immediately but several weeks or months later.

Ten and Eleven Year Olds

Children in this age range generally understand death as natural, inevitable, and universal. Consequently, these children often react to death in a manner very similar to adults.

Adolescents

Although this age group also reacts similarly to adults, many adolescents may exhibit various forms of denial. This usually takes the form of a lack of emotional display. Consequently, these young people may be experiencing sincere grief without any outward manifestations. It is important to encourage adolescents to discuss their feelings about death.

If you are having difficulty with your child's grief, please contact the clinic. We can provide assistance and contact numbers of professionals and support groups who can help you and your family.
